

FINAL PROJECT PROPOSAL

Team: Indrayudd Roy Chowdhury (120633249)

Topic: Driving Condition Classification

Dataset: BDD100K

road: dry; visibility: good

DATASET

BDD100K is a large scale driving video dataset, which comprises different scenes types, such as city, street, residential areas and highways. Moreover, it has been captured under various weather conditions and time of the day. The dataset contains 100K videos, each of which has been annotated at the 10-th frame, resulting in a total of 100K images manually annotated for a number of different tasks, including object detection or image segmentation. Each annotated image includes a label about the atmospheric weather condition (snowy, rainy, clear).

[This repository](#) has annotated this further into road and visibility conditions, which I plan to use for my project.

PROJECT

I will use a subset of the annotated BDD100K to classify between visibility conditions (Good/Bad) and road conditions (Wet, Dry, Snowy). This project is relevant because it has a lot of use and potential in the fields of autonomous vehicles. It also gives me the freedom to play around with multiple verticles of classification (visibility and road conditions) and the architectural decision making surrounding the same. This is also a usecase that I believe will benefit considerably from augmentated and synthetic data.

Thank you
